INFORMATION AROUND MEDICATION FOR THE MANAGEMENT OF DEPRESSION IN ADULTS IN PRIMARY CARE

Aims of this leaflet:

To assist Barnsley GPs with concise and practical information that is easy to use in a busy primary care setting.

This leaflet is not intended to supersede national guidance from organisations such as NICE, which is comprehensive or to serve as a substitute for the BNF / local formulary or shared care protocols.

This leaflet has been developed at the request of the Barnsley Area Prescribing Committee for use locally in Barnsley.

Antidepressant Medication:

- Antidepressant medication is not recommended for the management of mild depression.

- Antidepressant medication should be offered to patients with moderate depression and/or psychological interventions and appropriate monitoring should be implemented as per NICE guidelines.8

- A generic SSRI (common examples in this category include fluoxetine, citalopram and sertraline) should be used first line unless contraindicated. Second line options include a different generic SSRI or an alternative antidepressant (see algorithm). Venlafaxine (SNRI) can be considered where SSRIs have not been effective. Duloxetine should be reserved for patients in whom venlafaxine is not suitable.

- In patients with sleep disturbance, anxiety and depression, Mirtazapine may be a useful drug to consider. Possible weight gain is an issue.

- Venlafaxine is a useful antidepressant, but patients may experience a number of side effects including excessive sweating and symptoms of discontinuation, if stopped abruptly. It can also cause an increase or variation of blood pressure and hence this is something that needs to be monitored. Immediate release tablets (as opposed to extended release XL capsules) are more cost effective. If a once daily extended release preparation is indicated, XL tablets are more cost effective than XL capsules.

- Citalopram and escitalopram, are contraindicated in combination with either TCAs or antipsychotics and all drugs that cause QT prolongation. In the elderly (>65 years) the maximum daily dose of citalopram is 20mg and escitalopram 10mg.

- Post Myocardial Infarction and in patients with heart failure, Sertraline is the drug of choice for the treatment of depression.1

---

1 Taylor, D et al: Maudsley Prescribing Guidelines, 10th edition, Page 204
• In diabetics, use SSRIs as a first line antidepressant.

• In post stroke depression, SSRIs like Fluoxetine, Sertraline are widely recommended as is Mirtazapine.²

• If patient is on Warfarin, consider using Citalopram due to its probable lowest interaction potential.³

• The combination of Aspirin / NSAIDS with SSRIs increases rates of upper GI bleeding several fold.⁴ Consider prescribing a gastroprotective drug in older people who are taking NSAIDs or aspirin and a SSRI.

• Tricyclic antidepressants (TCAs) such as amitriptyline, dosulepin, imipramine, clomipramine have a higher number of adverse cardiovascular effects like arrhythmia, hypotension, tachycardia and QTc prolongation and more toxic in overdose. Avoid in cardiac disease.

• Dosulepin is no longer recommended as an antidepressant and should not be initiated in new patients. Evidence to support its tolerability relative to other antidepressants is outweighed by the increased cardiac risk and toxicity in overdose.

• If antidepressants are needed in pregnancy, SSRIs do not appear to be major teratogens with most data supporting the safety of fluoxetine.⁵

• In breast feeding, sertraline may be a reasonable option according to NICE guidelines.⁶

The following table indicates the costs⁷ of commonly prescribed antidepressants:

<table>
<thead>
<tr>
<th>Drug</th>
<th>28 day cost (dose cost based on)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Fluoxetine 20mg capsules</td>
<td>£1.05 (20mg daily)</td>
</tr>
<tr>
<td>Citalopram 20mg tablets</td>
<td>£1.11 (20mg daily)</td>
</tr>
<tr>
<td>Escitalopram 10mg tablets</td>
<td>£1.74 (10mg daily)</td>
</tr>
<tr>
<td>Sertraline 50mg tablets</td>
<td>£1.57 (50mg daily)</td>
</tr>
<tr>
<td>Sertraline 100mg tablets</td>
<td>£2.24 (100mg daily)</td>
</tr>
<tr>
<td>Mirtazapine 30mg tablets</td>
<td>£1.59 (30mg daily)</td>
</tr>
<tr>
<td>Venlafaxine 75mg tablets</td>
<td>£2.77 (75mg twice daily)</td>
</tr>
<tr>
<td>Venlafaxine 150mg XL tablets</td>
<td>£17.45 (150mg daily)</td>
</tr>
<tr>
<td>Venlafaxine 150mg XL capsules</td>
<td>£36.81 (150mg daily)</td>
</tr>
<tr>
<td>Duloxetine 30mg capsules</td>
<td>£20.91 (30mg daily)</td>
</tr>

⁷ Drug Tariff March 2015
⁸ Management of Depression in Primary and Secondary Care – NICE Clinical Guideline CG23 updated Oct 2009

Ratified by the Area Prescribing Committee April 2015.
Next review due: April 2017
Algorithm for Treatment of Depression with Antidepressants for Moderate or Severe Depression
(Augmentation, ECT and amber drugs to be started in secondary care)

For full prescribing information please refer to full Summary of Product Characteristics, the current BNF and local shared care guidelines where available.

Psychological Therapies at any stage e.g. CBT

Give therapeutic dose of antidepressant:
Consider a generic SSRI (e.g. fluoxetine) and see information on individual antidepressants. Discuss treatment choices with patient.

Give written information Consider:
• Type of symptoms
• Side effect profile
• Drug – Disease interactions e.g. consider sertraline in patients with ischaemic heart disease
• Drug - Drug interactions
• Discontinuation effects / suicidal thoughts and behaviour at initiation/dose increases

Assess over 2-4 weeks – longer in older people e.g. 6 weeks

Ineffective or not tolerated

• Titrate up the dose
• Change to a different antidepressant at therapeutic dose
• Consider a second generic SSRI, lofepramine, mirtazepine or moclobemide. If severe depression consider TCA or venlafaxine (not dosulepin)

Ineffective or not tolerated

• Augmentation Strategies – consider referral to secondary care
  o with Lithium – (ECG required prior to treatment)
  Add lithium to level of > 0.4mmol/L assess for at least 3 weeks
  o An antipsychotic e.g. oral risperidone
  o Another antidepressant e.g. add mirtazepine or mianserin to an SSRI – NB get pharmaceutical advice
• Other drugs to consider
  o phenelzine
  o high dose venlafaxine

Consider ECT for severe, life-threatening depression and when a rapid response is required, or when other treatments have failed.
Do not use ECT routinely for people with moderate depression but consider it if their depression has not responded to multiple treatments.

If good response and well tolerated, continue at therapeutic dose for at least 6 months, longer in older people.

Continue for longer (at least 2 years) in patients with recurring episodes.

Withdraw slowly where necessary.

Review diagnosis – consider:
• Compliance
• Social / family / environmental factors
• Alcohol misuse

May need further investigation:
• Referral to psychologist
• CT Scan
